# Chapter 1

## The Learning Problem

If you show a picture to a three-year-old and ask if there is a tree in it, you will likely get the correct answer. If you ask a thirty-year-old what the definition of a tree is, you will likely get an inconclusive answer. We didn't learn what a tree is by studying the mathematical definition of trees. We learned it by looking at trees. In other words, we learned from 'data'.

Learning from data is used in situations where we don't have an analytic solution, but we do have data that we can use to construct an empirical solution. This premise covers a lot of territory, and indeed learning from data is one of the most widely used techniques in science, engineering, and economics, among other fields.

In this chapter, we present examples of learning from data and formalize the learning problem. We also discuss the main concepts associated with learning, and the different paradigms of learning that have been developed.

---

## Chapter 2

# Training versus Testing

Before the final exam, a professor may hand out some practice problems and solutions to the class. Although these problems are not the exact ones that will appear on the exam, studying them will help you do better. They are the ‘training set’ in your learning.

If the professor’s goal is to help you do better in the exam, why not give out the exam problems themselves? Well, nice try 😊. Doing well in the exam is not the goal in and of itself. The goal is for you to learn the course material. The exam is merely a way to gauge how well you have learned the material. If the exam problems are known ahead of time, your performance on them will no longer accurately gauge how well you have learned.

The same distinction between training and testing happens in learning from data. In this chapter, we will develop a mathematical theory that characterizes this distinction. We will also discuss the conceptual and practical implications of the contrast between training and testing.

---

## Chapter 3

# The Linear Model

We often wonder how to draw a line between two categories; right versus wrong, personal versus professional life, useful email versus spam, to name a few. A line is intuitively our first choice for a decision boundary. In learning, as in life, a line is also a good first choice.

In Chapter 1, we (and the machine 😊) learned a procedure to ‘draw a line’ between two categories based on data (the perceptron learning algorithm). We started by taking the hypothesis set  $\mathcal{H}$  that included all possible lines (actually hyperplanes). The algorithm then searched for a good line in  $\mathcal{H}$  by iteratively correcting the errors made by the current candidate line, in an attempt to improve  $E_{\text{in}}$ . As we saw in Chapter 2, the linear model – set of lines – has a small VC dimension and so is able to generalize well from  $E_{\text{in}}$  to  $E_{\text{out}}$ .

The aim of this chapter is to further develop the basic linear model into a powerful tool for learning from data. We branch into three important problems: the classification problem that we have seen and two other important problems called *regression* and *probability estimation*. The three problems come with different but related algorithms, and cover a lot of territory in learning from data. As a rule of thumb, when faced with learning problems, it is generally a winning strategy to try a linear model first.

## Chapter 4

# Overfitting

Paraskavedekatriaphobia<sup>1</sup> (fear of Friday the 13th), and superstitions in general, are perhaps the most illustrious cases of the human ability to overfit. Unfortunate events are memorable, and given a few such memorable events, it is natural to *try* and find an explanation. In the future, will there be more unfortunate events on Friday the 13th's than on any other day?

Overfitting is the phenomenon where fitting the observed facts (data) well no longer indicates that we will get a decent out-of-sample error, and may actually lead to the opposite effect. You have probably seen cases of overfitting when the learning model is more complex than is necessary to represent the target function. The model uses its additional degrees of freedom to fit idiosyncrasies in the data (for example, noise), yielding a final hypothesis that is inferior. Overfitting can occur even when the hypothesis set contains only functions which are *far simpler* than the target function, and so the plot thickens 😊.

The ability to deal with overfitting is what separates professionals from amateurs in the field of learning from data. We will cover three themes: When does overfitting occur? What are the tools to combat overfitting? How can one estimate the degree of overfitting and ‘certify’ that a model is good, or better than another? Our emphasis will be on techniques that work well in practice.

---

<sup>1</sup>from the Greek *paraskevi* (Friday), *dekatreis* (thirteen), *phobia* (fear)

## Chapter 5

# Three Learning Principles

The study of learning from data highlights some general principles that are fascinating concepts in their own right. Having gone through the mathematical analysis and empirical illustrations of the first few chapters, we have a good foundation from which to articulate some of these principles and explain them in concrete terms.

In this chapter, we will discuss three principles. The first one is related to the choice of model and is called Occam's razor. The other two are related to data; sampling bias establishes an important principle about obtaining the data, and data snooping establishes an important principle about handling the data. A genuine understanding of these principles will protect you from the most common pitfalls in learning from data, and allow you to interpret generalization performance properly.
